

Spike? What Spike?

“Randy Merritt, *Send me your numbers and I’ll tell you what they say.*”

March 2026

“COVID vaccine mandates are necessary because the protected need to be protected from the unprotected by forcing the unprotected to use the protection that didn’t protect the protected. Get it?”

— — Steve Kirsch (<https://stevekirsch.substack.com/>)

The Cleveland Report was a compendium of statistics pulled together to summarize various performance findings that had accrued through the end of 2021; the end of that calendar year where numerous reports were published revealing a serious “spike” in those statistics.

The statistics were tracking the safety and effectiveness of various defense mechanisms applied during the COVID pandemic, including the new SARS-CoV-2 mRNA vaccine series.

This report is a short update offering a set of visualizations of statistics also drawn from the COVID pandemic. The graphs offered are from the VAERS (<https://vaers.hhs.gov/>) datasets up through 2023.

This report simply seeks to reinforce that calendar year 2021 was indeed *The Year of the Spike*.

VAERS Total Reports 1991 - 2023

The FDA/CDC jointly managed Vaccine Adverse Effect Reporting system went live in November 1990. Unlike *The Cleveland Report* the graphs contained herein are solely the work of the author. The reader may wish to conduct their own research to find similar plots to corroborate these findings.

We begin by showing that as America has continually added vaccines to it's vaccination inventory, each vaccine could be assumed to contribute some level to adverse effects. We clearly see a steady but relatively slow growth in adverse reports until 2021, where the reports submitted outright exploded. 2022 and even 2023 are clearly seen as significantly above the historical norm.

VAERS Reports vs Vaccines-in-Inventory by Year

Here we present a clearer picture of the growth of vaccines in the American program with the level of reports submitted against those vaccines, per year. It is a bit disheartening that starting in 2015 it appears the number of reports were at or over half the number of vaccines in inventory. Does this imply our vaccines were becoming more dangerous? Needless to say, check out calendar years 2021, 2022, and even 2023.

2021 VAERS Reports by Sex

One interesting statistic, that was published in the *The Cleveland Report*, was that women were 2.37 times more likely than men to suffer an adverse reaction from American vaccines.

Does anyone know why?

Patients Hospitalized by Vaccines 1991 - 2023

Now we settle into a series of graphs that show the history of severity in adverse reactions over time. Note the noticeable “bump” in 2007 through 2010.

Patients Disabled by Vaccines 1991 - 2023

Here we've gone from a vaccine injection putting a patient into the hospital to resulting in a disability. Were these disabilities eventually corrected?

Patient Deaths by Vaccines 1991 - 2023

The ultimate adverse reaction – you didn't survive the injection. Please note the scale of the y-axis. What happen to the Hippocratic Oath?

A relational join of the VAERS reports of 2021 with the vaccine table as of 2021 reveals the distribution of reports per vaccine. We order the report counts descending and show only the first 10 of those counts. The size in megabytes of the VAERS file that contains the adverse effects reports prior to 2021 were ~41 megabytes. The size of this file for 2021 alone measures 638 megabytes.

This size, along with the above graph, seals the conclusion that the “spike” of 2021 was caused by COVID-19 adverse reaction reports.

Comparison Counts of Adverse Events
Between COVID and non-COVID Vaccines in 2021

This is the distribution of the severity of adverse reactions to vaccines, further grouped by COVID versus non-COVID related vaccines. An interesting item in this plot is that the “spike” manifested across the severity levels.

We end our visualizations of the 2021 COVID pandemic with a final graph relating adverse reactions by vaccine manufacturer.

But a caveat must be introduced for this graph: it's not worth the paper it's written on. Indeed, one may argue it shouldn't be published at all. Why? Because, regrettably, the VAERS vaccine table does not include best-estimate of total doses administered to-date, with each release of the data.

We do this in demographic studies all the time. We must scale demographic comparisons on a *per capita* basis, in order to do a true comparison. One cannot compare demo statistics with Germany with those of Switzerland, since Germany has more Germans than Switzerland has Swiss. Traditionally, the per-capita scale is per 100,000 of population.

This graph needs to scale it's counts as a percentage of doses administered. For all we know, the Janssen variant may be twice as lethal than the Moderna variant *as a percent of doses actually administered*. Perhaps the current heads of the FDA, CDC, and NIH will work to correct this shortcoming.
